# Open induction

The **open induction arithmetic** (**IOpen**) is the formal arithmetical theory in the language  $L = \langle 0, 1, +, -, \cdot, \leq \rangle$  axiomatized by a set of elementary properties of  $0, 1, +, -, \cdot, \leq$  and by the scheme of axioms of open induction:

$$(\varphi(0, \bar{y}) \ \& \ (\forall x)(\varphi(x, \bar{y}) \rightarrow \varphi(x + 1, \bar{y}))) \rightarrow (\forall x)\varphi(x, \bar{y}),$$

for all **open** (i.e. quantifier free) formulas  $\varphi$  of  $L$ .

The axioms ensure that any model  $\mathcal{M}^+$  of IOpen is the nonnegative part of the unique **discretely ordered ring**  $\mathcal{M}$ .

We often say that a discretely ordered ring  $\mathcal{M}$  is a model of IOpen, by which we mean that its nonnegative part  $\mathcal{M}^+$  is.

# The Shepherdson's theorem

**Question:** Is there an algebraic characterisation of those discretely ordered rings that are models of  $\text{IOpen}$ ?

Theorem (J. C. Shepherdson, 1964)

*A discretely ordered ring is a model of  $\text{IOpen}$  if and only if it is an integer part of its real closure.*

The **real closure**  $R(\mathcal{M})$  of a discretely ordered ring  $\mathcal{M}$  is the unique (ordered) **real closed field** extending the ordered **fraction field**  $F(\mathcal{M})$  of  $\mathcal{M}$ .

A discretely ordered subring  $I$  of  $\mathcal{R}$  is called an **integer part** of  $\mathcal{R}$  (denoted by  $I \subseteq^{IP} \mathcal{R}$ ) if for every  $r \in \mathcal{R}$ , there is  $i \in I$  such that  $r - 1 < i \leq r$ . Such an  $i$  is called the **integer part** of  $r$  (w.r.t.  $I$ ).

# Integer-parts-of-roots property

Let  $f(x)$  be a definable unary function on  $\mathcal{M}$ . By  $\text{IPR}(f)$  (*integer-parts-of-roots*) we denote the following formula:

$$(a < b \ \& \ f(a) \leq y < f(b)) \rightarrow (\exists x)(a \leq x < b \ \& \ f(x) \leq y < f(x+1)).$$

The intended meaning of  $\mathcal{M} \models \text{IPR}(f)$  can be expressed in vague terms as “existence of integer parts for all  $f$ -roots of values  $y \in M$ ”.

If  $\mathcal{F}$  is a set of definable unary functions on  $\mathcal{M}$ , we write  $\text{IPR}(\mathcal{F})$  for the scheme  $\{\text{IPR}(f); f \in \mathcal{F}\}$ .

# The Shepherdson's theorem reformulated

We can stratify Shepherdson's theorem a little bit more:

Theorem (J. C. Shepherdson, 1964)

*The following are equivalent for any discretely ordered ring  $\mathcal{M}$ :*

- 1  $\mathcal{M} \subseteq^{IP} R(\mathcal{M})$ ,
- 2 all roots  $r \in R(\mathcal{M})$  of polynomials  $p \in \mathcal{M}[x]$  have integer parts in  $\mathcal{M}$ ,
- 3  $\mathcal{M} \models \text{IPR}(\mathcal{M}[x])$ ,
- 4  $\mathcal{M}^+ \models \text{IOpen}$ .

# Presburger arithmetic

The **Presburger arithmetic** ( $\text{Pr}$ ) is the formal arithmetical theory in the language  $L^+ = \langle 0, 1, +, -, \leq \rangle$  axiomatized by a set of elementary properties of  $0, 1, +, -, \leq$  and by the scheme of axioms of induction:

$$(\varphi(0, \bar{y}) \ \& \ (\forall x)(\varphi(x, \bar{y}) \rightarrow \varphi(x + 1, \bar{y}))) \rightarrow (\forall x)\varphi(x, \bar{y}),$$

for **all** formulas  $\varphi$  of  $L^+$ .

Every model of  $\text{Pr}$  is the nonnegative part of the unique **discretely ordered additive Abelian group**.

# “Shepherdson’s theorem” for Presburger arithmetic

## Theorem

Let  $\mathcal{M}$  be a discretely ordered additive Abelian group. Then the following are equivalent:

- 1  $\mathcal{M} \subseteq \text{IP} \frac{M}{\mathbb{N}}$ ,
- 2 all fractions  $m/n$  with  $m \in M$  and  $0 \neq n \in \mathbb{N}$  have integer parts in  $M$ ,
- 3  $\mathcal{M} \models \text{IPR}(\{n(x); n \in \mathbb{N}\})$ , where  $n(x) = x + \dots + x$  with  $n$  summands,
- 4  $\mathcal{M}^+ \models \text{Pr}$ .

# The Shepherdson's theorem reformulated

Let us recall the Shepherdson's theorem for IOpen:

Theorem (J. C. Shepherdson, 1964)

*The following are equivalent for any discretely ordered ring  $\mathcal{M}$ :*

- 1  $\mathcal{M} \subseteq^{IP} R(\mathcal{M})$ ,
- 2 all roots  $r \in R(\mathcal{M})$  of polynomials  $p \in \mathcal{M}[x]$  have integer parts in  $\mathcal{M}$ ,
- 3  $\mathcal{M} \models \text{IPR}(\mathcal{M}[x])$ ,
- 4  $\mathcal{M}^+ \models \text{IOpen}$ .

The property  $\mathcal{M} \subseteq^{IP} R(\mathcal{M})$  is equivalent to

$$\mathcal{M} \subseteq^{IP} F(\mathcal{M}) \ \& \ F(\mathcal{M}) \subseteq^d R(\mathcal{M}),$$

where  $R' \subseteq^d R$  denotes that  $R'$  is a **dense subring** of  $R$ , i.e. for every  $q < r$  from  $R$  there is  $r' \in R'$  such that  $q < r' < r$ .

# Open linear induction

The theory corresponding (in a Shepherdson-like way) to the property  $\mathcal{M} \subseteq^{IP} F(\mathcal{M})$  is the the **open linear induction arithmetic**.

The **open linear induction arithmetic** (**IOpenLin**) is the formal arithmetical theory in the language  $L = \langle 0, 1, +, -, \cdot, \leq \rangle$  axiomatized by a set of elementary properties of  $0, 1, +, -, \cdot, \leq$  and by the scheme of axioms of open linear induction:

$$(\varphi(0, \bar{y}) \ \& \ (\forall x)(\varphi(x, \bar{y}) \rightarrow \varphi(x + 1, \bar{y}))) \rightarrow (\forall x)\varphi(x, \bar{y}),$$

for all **open** (i.e. quantifier free) linear formulas  $\varphi$  of  $L$ .

The formula  $\varphi(x, \bar{y})$  is called **linear** if in every occurrence of  $\cdot$  in  $\varphi$  at least one of the two factors is  $y_i$ , for some  $i$ .

## Theorem

Let  $\mathcal{M}$  be a discretely ordered ring. Then the following are equivalent:

- 1  $\mathcal{M} \subseteq^{IP} F(\mathcal{M})$ ,
- 2 all fractions  $m'/m$  with  $m', m \in M$  and  $0 < m$  have integer parts in  $M$ ,
- 3  $\mathcal{M} \models \text{IPR}(\{m(x); m \in M\})$ , where  $m(x) = m \cdot x$ ,
- 4  $\mathcal{M} \models (\forall n, k \neq 0)(\exists n')(\exists 0 \leq l < k)(n = n' \cdot k + l)$ ,
- 5  $\mathcal{M}^+ \models \text{IOpenLin}$ .

# Open eventual induction

There is a theory that corresponds to the property  $F(M) \subseteq^d R(\mathcal{M})$  as well. However, it is not given by a scheme of induction, but by certain generalization of it - the scheme of **open eventual induction**.

The  **$l$ -step induction axiom** for the formula  $\varphi(x, \bar{y})$  is the following formula denoted by  $I'_x\varphi(x, \bar{y})$  or simply  $I'_x\varphi$ :

$$((\forall u < l)\varphi(u, \bar{y}) \wedge (\forall v)(\varphi(v, \bar{y}) \rightarrow \varphi(v + l, \bar{y}))) \rightarrow (\forall x)\varphi(x, \bar{y}).$$

The **open eventual induction arithmetic** (**eIOpen**) is the formal arithmetical theory in the language  $L = \langle 0, 1, +, -, \cdot, \leq \rangle$  axiomatized by a set of elementary properties of  $0, 1, +, -, \cdot, \leq$  and by the scheme of axioms of open eventual induction:

$$(\exists l > 0)(I'_x\varphi(x/l, \bar{y})),$$

for all **open** (i.e. quantifier free) formulas  $\varphi$  of  $L$ .

## Theorem

Let  $\mathcal{M}$  be a discretely ordered ring. Then the following are equivalent:

- 1  $F(\mathcal{M}) \subseteq^d R(\mathcal{M})$ ,
- 2  $(\forall r \in R(\mathcal{M}))(\exists f \in F(\mathcal{M}))(r < f < r + 1)$ ,
- 3  $(\forall r \in R(\mathcal{M}))(\exists l, m \in M)(m \leq lr < m + l)$ ,
- 4  $\mathcal{M}^+ \models \text{eIOpen}$ .

# Alternative axiomatization of IOpen

As we know that

$$(\mathcal{M} \subseteq^{IP} F(\mathcal{M}) \ \& \ F(\mathcal{M}) \subseteq^d R(\mathcal{M})) \rightarrow \mathcal{M} \subseteq^{IP} R(\mathcal{M}),$$

we get the following alternative axiomatization of IOpen:

Corollary

$\text{IOpen} = \text{IOpenLin} + \text{eIOpen}.$

Note that similarly from the inclusion

$$\text{IOpen} \supseteq \text{IOpenLin} + \text{eIOpen},$$

we get:

Corollary

$(\mathcal{M} \subseteq^{IP} F(\mathcal{M}) \ \& \ F(\mathcal{M}) \subseteq^d R(\mathcal{M})) \leftrightarrow \mathcal{M} \subseteq^{IP} R(\mathcal{M}).$

## Open questions:

Is there a truly general Shepherdson's theorem, i.e. a theorem such that all variants of Shepherdson theorems for various theories are its special cases?

Are there variants of the Shepherdson's theorem for theories stronger than  $\text{IOpen}$ ?

Thank you for your attention.
